

Toronto 2023 Monthly Death Registry*

Yunzhao Li

January 25, 2024

In Toronto, there are many people who die each year. The data of death registry supports the City's operational requirements and business functions. In this paper we will make a table of the number of death in Toronto for each month in 2023. By analyzing this, we can find months with a high number of deaths and make conjectures with factors like weather, policies or incidents of that particular month.

1 Introduction

Death is a topic that people are not often willing to talk about, but it is closely related to the City's operational requirements, business functions as well as social resource allocation, so it is necessary to understand the data of death registration and do some basic statistical analysis of it.

The data source in this study was obtained by opendatatoronto, from which the data of the Toronto area in 2023 were selected for research and analysis. We expect to produce a table reflecting the number of deaths registered in the Toronto area in each month of 2023, and correlate the data with related factors.

These speculation may help in the formulation of future policies, such as whether the death toll is higher in the colder months, then the government can increase investment in the construction of shelters, if it is because of the epidemic in certain months, then it can be prevented according to the relevant month and transmission trend, formulate a mask-related policy or appropriately restrict travel, or because of some large-scale accident that caused a large number of new deaths, appropriate measures can be put in place to improve the level of safety. Which months have a low number of deaths can also be related to the input of some public resources, per capita income, and the level of social welfare, which in turn can be used to judge whether these policies and improvements are significant, whether people's quality of life and income are stable, and whether social security is good. The government can regulate these factors to reduce the number of deaths caused by non-aging, which is the long-term significance of this study.

This study will end with these numbers documenting the lives that have accompanied the city and telling their stories implicitly to some extent.

2 Data

This dataset includes information relating to the registration of deaths documented by Registry Services staff located in four of the civic centres (Scarborough, North York, Toronto and Etobicoke). Registration of death data is entered into the Registry Services Tracking System (RSTS), from which aggregate statistical information is generated to create the dataset. The dataset resides in an Oracle database in the City's environment.

The dataset is created in support of the Vital Statistics Act, which is a Provincial legislation. The dataset also supports the City's operational requirements and business functions.

The details of the data sources are shown here: Data quality score beta: Gold, Data last refreshed: Jan 1, 2024, Refreshed: Monthly, Data type: Table, Topics: Health, License: Open Government License - Toronto

<https://open.toronto.ca/dataset/death-registry-statistics/>

The original data has five columns, and the column name and introduction are as followed:

row: identifier for Open Data database,

CIVIC_CENTRE: Civic centre code,

DEATH_LICENSES: Number of deaths registered in the month,

PLACE_OF_DEATH: Place where death occurred,

TIME_PERIOD: Month death registered. Their classes are separately: numeric, character, numeric, character and numeric.

Depending on our expectation, only two columns named time_period and death_license after filtering by region and time period are needed. This column of data, called the time period, is presented in the form of yyyy-mm characters. After that, we need to modify it to date and count the summarized data by month. The column, titled Death Certificate, is presented in numeric form, with a maximum value of 2007 and a minimum value of 1, reflecting a single record of local deaths over each time period. And for the column called place_of_death, can be used to filter out death records in the Toronto area.

This is the basic description of the data of interests. The appendix shows the process of simulating, reading, cleaning, and creating tables of data in details.

3 Results

To create the table we expect follows this procedure: simulate with a dataset, read the raw data, clean the data, and finally the data was accurately presented and consistent with the sketch we made. The number of deaths in each month is as followed:

January: 1083, February: 485, March: 1012, April: 1677, May: 2008, June: 1928, July: 417, August: 912, September: 1268, October: 1182, November: 1458, December: 611.

We found that the highest number of deaths was in May and June, with a high of around 2,000, and the lowest months were in February, July and December, with around 500. The death toll in the remaining months was concentrated around 1,000.

Combined with the ideas introduced at the beginning of the article, this data can be combined with other relevant data to analyze, and perhaps unexpected discoveries can be obtained. This is the direction of future research that can be further explored, and this data can be used as a basis. We can also drill down into other years' data, or trends in total deaths over several years, to create a line chart.

The result of our code are shown by Table 1.

Table 1: Number of death in Toronto for each month in 2023

Month	Number of death
January	1083
February	485
March	1012
April	1677
May	2008
June	1928
July	417
August	912
September	1268
October	1182
November	1458
December	611

4 Conclusion

Overall, this study successfully plotted the number of deaths registered in Toronto by month in 2023, and achieved the expected results. The highest number of deaths was concentrated in May and June, with a high of around 2,000, and the lowest months were in February, July and December, with a low of around 500. The death toll in the remaining months was concentrated around 1,000. It is believed that data can be used to assist in government management, policy formulation, and improvement of people's livelihood.

Appendix

A Additional data details

A.1 Simulation

We simulated the dataset using the `tibble` function and determined the feasibility of the plan. The top 6 rows are shown by Table 2

Table 2: Dataset Simulation

time period	place_of_death	death_number
2023-01	Toronto	51
2023-02	Toronto	46
2023-03	Toronto	48
2023-04	Toronto	64
2023-05	Toronto	69
2023-06	Toronto	53

A.2 Read raw data

We downloaded a csv document which documents the data of this topic: About Death Registry Statistics from `opendatatoronto` as raw data.

The top 6 rows are shown by Table 3

Table 3: Raw Death Registry

_id	CIVIC_CENTRE	DEATH_LICENSES	PLACE_OF_DEATH	TIME_PERIOD
19435	ET	69	Outside City Limits	2011-01
19436	ET	341	Toronto	2011-01
19437	NY	141	Outside City Limits	2011-01
19438	NY	540	Toronto	2011-01
19439	SC	129	Outside City Limits	2011-01
19440	SC	545	Toronto	2011-01

A.3 Clean data

The purpose of this step is to filter out the two columns of data we need for the Toronto area and the time period in 2023, in preparation for the table we about to create. First, the `clean_names` function was called to change the column name to lowercase and use underlines to split the words. Then, we converted the class of time period from character to date and filtered the data of death register in Toronto happened in 2023 by listing all possible month data. Finally, selected the two columns we need, which is `time_period` and number of `death_license`.

The top 6 rows are shown by [Table 4](#)

Table 4: Cleaned Death Registry

time_period	death_licenses
2023-01-01	20
2023-01-01	1015
2023-01-01	48
2023-02-01	12
2023-02-01	446
2023-02-01	27

A.4 Tests

Three tests were written to check whether the cleaned death registry data suits our expectation. We separately tested the `time_period`'s value and class, `death_license`'s value and class.
